# Logic Functions over Galois Field GF(4) 

Zensho NaKAO*

#### Abstract

The elements of Galois field $\mathrm{GF}(4)$ are represented by four numerals $\{0,1,2,3\}$; it is shown that all quaternary logic functions can be expressed in a sort of standard form as polynomial functions over $G F(4)$; the two field operators of $\mathrm{GF}(4)$ are proposed as basic logic gates and are used as basic building blocks in the representation of the logic functions.

## 1. Introduction

In recent papers, Hachimine and Zukeran [HZ1] proposed a set of four-valued logic functions and demonstrated the completeness of the system; they also designed several quaternary logic circuits [HZ2].

The objective of this note is to show that how Galois field GF(4) (i.e., a finite field of four elements) can be used effectively to represent quaternary logic functions such as the ones studied in [ $\mathrm{HZ} 1, \mathrm{HZ} 2$ ] in standard polynominal forms as was done in [N1, NZK].

## 2. Preliminaries

The set $A_{2}=\{0,1\}$ of two symbols 0,1 can be made into a Boolean algebra by furnishing it with two binary operations $V, \wedge$ and one unary operation ${ }^{-}$which are defined by the following (truth) tables:

| $V$ | 0 | 1 |
| :---: | :---: | :---: |
| 0 | 0 | 1 |
| 1 | 1 | 1 |

| $\wedge$ | 0 | 1 |
| :--- | :--- | :--- |
| 0 | 0 | 0 |
| 1 | 0 | 1 |

| $x$ | $\bar{x}$ |
| :---: | :---: |
| 1 | 0 |
| 0 | 1 |

Table 1. Boolean operators
On $A_{2}$, introduce two binary operations + , • (or juxtaposition) by the (truth) tables:

| + | 0 | 1 |
| :---: | :---: | :---: |
| 0 | 0 | 1 |
| 1 | 1 | 0 |

| $\cdot$ | 0 | 1 |
| :--- | :--- | :--- |
| 0 | 0 | 0 |
| 1 | 0 | 1 |

Table 2. Field operators

Received: October 31, 1984
*Department of Electronics Engineering and Computer Science

The algebraic operations now transform the structure on $A_{2}$ into that of Galois field GF(2). In fact, the Boolean algebraic structure ( $\mathrm{A}_{2} ; \vee, \wedge,{ }^{-}$) and the field structure ( $\mathrm{GF}(2) ;+, \bullet$ ) are related by the following transformation formulas:

$$
\begin{array}{ll}
x \wedge y=x y & x y=x \wedge y \\
x \vee y=x+y+x y & x+y=(x \wedge \bar{y}) \vee(\bar{x} \wedge y) \\
\bar{x}=x+1 &
\end{array}
$$

Since GF(2) is a field, the operations in Table 2 define subtraction and division implicitly (namely , the charts are used backward), which are the operations impossible in the Boolean algebra $\mathrm{A}_{2}$. Also, it is known in field theory that we can always enlarge $\operatorname{GF}(2)$ to the extension field $\operatorname{GF}\left(2^{\mathrm{n}}\right)$ ( n is a natural number) which possesses exactly $2^{n}$ elements by adjoining a zero of some irreducible polynomial over GF(2).

In this note we let $n=2$ and use $G F(4)$ in studying $A_{4}=\{0,1,2,3\}$ with a quaternary logic structure. We can obtain $\mathrm{GF}(4)$ as the splitting field of the irreducible polynomial $p(x)=x^{2}+x+1$ over $\operatorname{GF}(2)$ by adjoining a solution $\alpha$ of $p(x)=0$ in an extension field of $\operatorname{GF}(2)$. Since $G F(4)$ is a two dimensional vector field over $\operatorname{GF}(2)$ with the base $\{1, \alpha\}$, where $\alpha^{2}=\alpha+1, \operatorname{GF}(4)$ has four elements $0,1, \alpha, \alpha+1$. For ease of reference and computation, we introduce two numerals 2 and 3 , and let $\alpha=2$ and $\alpha+1=3$; we obtain the following addition and multiplication tables which are in fact the truth tables for the binary operations:

| + | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 1 | 2 | 3 |
| 1 | 1 | 0 | 3 | 2 |
| 2 | 2 | 3 | 0 | 1 |
| 3 | 3 | 2 | 1 | 0 |

| $\cdot$ | 0 | 1 | 2 | 3 |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | 0 |
| 1 | 0 | 1 | 2 | 3 |
| 2 | 0 | 2 | 3 | 1 |
| 3 | 0 | 3 | 1 | 2 |

Table 3. Field operators
Recall that (GF(4); + ) is Klein's Viergruppe (hence, not cyclic), and that (GF(4) - \{0\}; $\boldsymbol{\bullet}$ ) is a cyclic group of order 3; both are Abelian (i.e., the tables are symmetric with respect to the main diagonal).

It is to be noted that there are quaternary logic functions on $A_{4}$ which cannot be expressed as standard Boolean functions, i.e., $\left(A_{4} ; V, \wedge,{ }^{-}\right)$is not a complete system.

In the rest of the section, we quote the necessary results from Galois theory:

$$
\begin{equation*}
(x+y)^{2}=x^{2}+y^{2} \forall x, y \in G F(4) \tag{2}
\end{equation*}
$$

$$
\begin{equation*}
x+x=0 \forall x \in G F(4) \tag{3}
\end{equation*}
$$

Any function from a finite field into itself is known to be a polymomial function (use Lagrange's interpolation formula, for example); the following results give us the necessary formulas for our specific purpose [T]:
(4) If $\mathrm{f}: \mathrm{GF}(4) \longrightarrow \mathrm{GF}(4)$ is a function, then $f$ can be expressed in a polynomial form over GF(4):

$$
f(x)=a_{0}+a_{1} x+a_{2} x^{2}+a_{3} x^{3}
$$

where $a_{0}=f(0), a_{i}=\sum_{x \in G F(4)} x^{3-i} f(x),(1 \leq i \leq 3)$.
(5) If $\mathrm{f}: \mathrm{GF}(4) \times \mathrm{GF}(4) \longrightarrow \mathrm{GF}(4)$ is a mapping, then f can be realized as a polynomial mapping over $\mathrm{GF}(4)$ in two variables:

$$
f(x, y)=\sum_{0 \leq i, j \leq 3} a_{i j} x^{i} y^{j}
$$

where $a_{00}=f(0,0), a_{i 0}=\sum_{x \in G F(4)} x^{3-i} f(x, 0), a_{0 i}=\sum_{y \in G F(4)} y^{3-i} f(0, y)$,
$a_{i j}=\sum_{x, y \in G F(4)} x^{3-i} y^{3-j} f(x, y),(1 \leq i, j \leq 3)$.
Note that in formulas (4) and (5) above, all calculations must be done in Galois field GF(4), and also that (5) can be generalized to mappings

$$
\mathrm{f}: \mathrm{GF}(4)^{\mathrm{n}} \longrightarrow \mathrm{GF}(4)
$$

of $n(\geq 1)$ variables. With this rigid structure, we will be able to express all quaternary logic functions as polynomial functions on $G F(4)$ or $G F(4)^{2}$ (or $G F(4)^{n}$, if necessary) of total degree at most 6.

## 3. Translation of $A_{4}$ to GF(4)

It is proved that (MIN, MAX, $x^{(0,1)}, 1,2$ ) forms a complete system of quaternary logic functions in [HZ1]; we are going to express all those quaternary logic functions explicitly as polynomials over $\mathrm{GF}(4)$, which is a consequence of the evident fact that ( $\mathrm{GF}(4) ;+, \bullet)$ is another complete system of quaternary logic functions. The BASIC programs used are included in the Appendix.
a. $\operatorname{MIN}[x, y]$

Operation tables for the binary operators $\operatorname{MIN}[x, y]$ and $\operatorname{MAX}[x, y]$ are given below:

| MIN | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 |
| 1 | 0 | 1 | 1 | 1 |
| 2 | 0 | 1 | 2 | 2 |
| 3 | 0 | 1 | 2 | 3 |

| MAX | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 1 | 2 | 3 |
| 1 | 1 | 1 | 2 | 3 |
| 2 | 2 | 2 | 2 | 3 |
| 3 | 3 | 3 | 3 | 3 |

Table 4. MIN and MAX operators

By using formulas for $a_{i j}$ in (5), we can obtain the following results:

$$
\begin{align*}
& a_{00}=a_{01}=a_{10}=a_{02}=a_{20}=a_{03}=a_{30}=a_{11}=a_{33}=0  \tag{6}\\
& a_{22}=1, \quad a_{12}=a_{21}=a_{13}=a_{31}=2, \quad a_{23}=a_{32}=3
\end{align*}
$$

Thus we get a polynomial expression for $\operatorname{MIN}[x, y]$ :

$$
\begin{equation*}
\operatorname{MIN}[x, y]=2 x y^{2}+2 x y^{3}+2 x^{2} y+2 x^{3} y+x^{2} y^{2}+3 x^{2} y^{3}+3 x^{3} y^{2} \tag{7}
\end{equation*}
$$

By using (2) and collecting like terms, we can change $\operatorname{MIN}[x, y]$ into a less formidable poly. nomial in elementary symmetric functions $(x+y)$ and ( $x y$ ):

$$
\begin{equation*}
\operatorname{MIN}[x, y]=x y\left\{2(x+y)+2(x+y)^{2}+x y[1+3(x+y)]\right\} \tag{8}
\end{equation*}
$$

b. $\operatorname{MAX}[x, y]$

Computing similarly as in MIN $[x, y]$, we can derive the following results:

$$
\begin{align*}
& a_{00}=a_{02}=a_{20}=a_{03}=a_{30}=a_{11}=a_{33}=0, a_{23}=a_{32}=3  \tag{9}\\
& a_{01}=a_{10}=a_{22}=1, a_{12}=a_{21}=a_{13}=a_{31}=2
\end{align*}
$$

Therefore, a polynomial expression for $\operatorname{MAX}[x, y]$ is:

$$
\begin{equation*}
\operatorname{MAX}[x, y]=x+y+2 x^{2} y+2 x y^{2}+2 x^{3} y+2 x y^{3}+x^{2} y^{2}+3 x^{3} y^{2}+3 x^{2} y^{3} \tag{10}
\end{equation*}
$$

Rewriting the result above as a polynomial in $(x+y)$ and ( $x \dot{y}$ ), we get:

$$
\begin{equation*}
\operatorname{MAX}[x, y]=(x+y)+x y\left[2(x+y)+2(x+y)^{2}+x y+3 x y(x+y)\right] \tag{11}
\end{equation*}
$$

c. $x^{(0,2)}$

The unary operator $x^{[0,2]}$ is defined by:

$$
\begin{align*}
x^{[0,2]} & =3 \text { if } x \in\{0,2\}  \tag{12}\\
& =0 \text { otherwise }
\end{align*}
$$

A truth table for the operator is given below:

| $x$ | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
| $x^{(0,2)}$ | 3 | 0 | 3 | 0 |

Table 5. Truth table for ${ }^{[0,2]}$
Repeated applications of the formulas for $a_{i}$ in (4) yield:

$$
\begin{equation*}
a_{0}=3, \quad a_{1}=2, \quad a_{2}=1, \quad a_{3}=0 \tag{13}
\end{equation*}
$$

Hence, we obtain a polynomial function for $\mathrm{x}^{[0,2]}$ :

$$
\begin{equation*}
x^{\{0,2\}}=3+2 x+x^{2}=(1+x)(3+x) \tag{14}
\end{equation*}
$$

Putting pieces obtained together, we demonstrated that the algebraic structure (GF(4);,$+ \bullet$ ) provides an effective method for deriving standard forms of the quaternary logic functions.

## 4. Other translations

For completeness of presentation, we include the polynomial formulas for the binary operator $\operatorname{NOR}[x, y]$; the unary operators ${ }^{(k)} x$ and $x^{(k)}$ which are discussed in [HZ2]. Their definitions follow:

$$
\begin{align*}
& \text { NOR }[x, y]=3+\operatorname{MAX}[x, y]  \tag{15}\\
& \begin{aligned}
&(k) \\
& x \equiv x+k(\bmod 4), \quad k=0,1,2,3 \\
& x^{(k)}=3 \text { if } x=k \quad k=0,1,2,3 \\
&=0 \text { otherwise }
\end{aligned} \tag{16}
\end{align*}
$$

Polynomial representations for the operators are given in the following:

$$
\begin{align*}
\operatorname{NOR}[x, y] & =3+\operatorname{MAX}[x, y] \\
& =3+(x+y)+x y\left[2(x+y)+2(x+y)^{2}+x y+3 x y(x+y)\right]  \tag{18}\\
(k) & =(x+k)+x k[3+2(x+k)+x k], \quad k=0,1,2,3  \tag{19}\\
x^{(k)} & =3\left[1+(x+k)^{3}\right], \quad k=0,1,2,3 \tag{20}
\end{align*}
$$

## 5. Conclusions

We found that all quaternary logic functions of one or two variables can be realized as polynomial functions over Galois field $G F(4)$ in one or two variables of total degree at most 6 . An obvious advantage for having polynomial expressions is that we can formally manipulate the elements of $A_{4}$, i.e., $\mathrm{GF}(4)$ with four arithmetic operations of $\mathrm{GF}(4)$ itself as we normally do with the real (or complex) number field.

If we can design $(x+y)$ and ( $x y$ ) as basic logic circuit elements*, then we can easily construct other circuits such as MIN, MAX, $x^{[0,2\}}$, NOR, ${ }^{(k)} x$ and $x^{(k)}$. For illustration, take MIN, MAX and $x^{\{0,2\}}$. We introduce two logic gate symbols for the operators $(x+y)$ and ( $\left.x y\right)$ :

Figure 1. Circuit symbols for $(x+y)$ and ( $x y$ )

Then the following diagrams present one possible design for each function:

[^0]

Figure 2. MIN $[x, y]$ gate

Figure 3. $\operatorname{MAX}[x, y]$ gate

Figure 4. Logic gate for $\mathrm{x}^{\{0,2\}}$

Some properties of quanternary logic functions over $\mathrm{GF}(4)$ will be discussed further in the forthcoming paper [ N 2 ].

## b. Logic gates

Figure A. 1. $(x+y)$ gate

Figure A.2. (xy) gate

[^0]:    *The logic circuit elements were designed by Mr. Chotei Zukeran, Department of Electrical Engineering, Ryukyu University; and are included as Figures in the Appendix.
